

Lecture 17: Integration

As recalled in Lecture 12, the course is structured in two parts. The first part, organised under the slogan "space as a stage for things" emphasised the following concepts:

- metric space, topological space, symmetry groups, continuity, constructing new spaces from old ones, compactness, Hausdorff spaces.

The second part, "space as a stage for motion", has been organised around the concept of a function space. With Picard's theorem in Lecture 15 we got a glimpse of the fundamental role such spaces play in the study of dynamics. But something is missing. Recall from Lecture 16 that by the Stone-Weierstrass theorem the trigonometric polynomials are dense in $C(S^1, \mathbb{R})$. But this result is not constructive (although, see Ex. L16-5) in the sense that it does not tell us, given $f: S^1 \rightarrow \mathbb{R}$ continuous, a "preferred" coefficient a_n of $\cos(n\theta)$ in an approximating polynomial for f .

Compare this to the situation for a vector v in a vector space V with basis $\{u_1, \dots, u_m\}$. There is a unique expression of v as $\sum_{i=1}^m a_i u_i$ for $a_i \in \mathbb{R}$, and the coefficients are "read off" by the linear functionals $u_i^* \in V^*$ which send v to $u_i^*(v) = a_i$. These functionals tell us "how much" of v is in the direction u_i .

We know $C(S^1, \mathbb{R})$ is an \mathbb{R} -vector space, and it is not difficult to show that $\{\cos(n\theta), \sin(n\theta)\}_{n \geq 1} \cup \{1\}$ is a linearly independent set in this vector space (see Ex. L16-2 and L17-1 below). So it is natural to ask: is this a basis for the (infinite-dimensional) vector space $C(S^1, \mathbb{R})$? One might then think a dual basis $\cos(n\theta)^*$ could produce the desired coefficient a_n .

However, this is far too naive: the trigonometric polynomials do not span $C_b(S^1, \mathbb{R})$ and even if they did, in the infinite-dimensional case we do not have a dual basis. Too bad! We seem to lack some basic conceptual framework for working constructively in infinite-dimensional vector spaces of this kind. The appropriate framework, whose study will occupy us for the remainder of the semester, is Hilbert space, and the Hilbert space structure on $C_b(S^1, \mathbb{R})$ (or rather a suitable replacement denoted $L^2(S^1)$) is derived from the integral.

In today's lecture we develop integrals in the context of function spaces, which will lead us to L^2 spaces, whose structure we will axiomatise next lecture using the notion of a Hilbert space.

Exercise L17-1 With $S^1 = \mathbb{R}/2\pi\mathbb{Z}$ prove the set $\{\cos(n\theta), \sin(n\theta)\}_{n>1} \cup \{1\}$ is linearly independent in $C_b(S^1, \mathbb{R})$ (so the expressions in eqⁿ (7.1) of Lecture 16 are unique). In particular this shows that $C_b(S^1, \mathbb{R})$ is infinite-dimensional.

Exercise L17-2 Prove $e^{\cos(\theta)} \in C_b(S^1, \mathbb{R})$ is not in the linear span of the linearly independent set considered in the previous exercise.

Defⁿ An integral pair (X, \int) is a compact Hausdorff space X together with a function $\int : C_b(X, \mathbb{R}) \rightarrow \mathbb{R}$ which is linear and continuous, and satisfies for all $f \in C_b(X, \mathbb{R})$:

(i) If $f \geq 0$ then $\int f \geq 0$, and

[where $f \geq 0$ means for all $x \in X$ $f(x) \geq 0$]

(ii) if $f \geq 0$ then $\int f = 0$ if and only if $f = 0$.

Lemma L17-0 For $a < b$ the Riemann integral $\int_{[a,b]} : Cts([a,b], \mathbb{R}) \rightarrow \mathbb{R}$ gives an integral pair $([a,b], \int_{[a,b]})$.

Proof As usual $Cts([a,b], \mathbb{R})$ has the compact-open topology (and metric d_∞), see Tutorial 8 for a reminder on definitions. For linearity see T. Tao "Analysis I" Theorem 11.4.1 (a), (b). Condition (i) is immediate from the definitions.

For (ii) suppose $\int_{[a,b]} f = 0$ and that $f(x_0) > 0$. Then $f^{-1}((\frac{1}{2}f(x_0), \infty))$ is an open neighborhood of x_0 , which contains a closed interval, say

$$x_0 \in [c, d] \subseteq f^{-1}((\frac{1}{2}f(x_0), \infty)) \subseteq [a, b] \quad (c \neq d)$$

Then $\mathcal{P} = \{[a, c), [c, d], (d, b]\}$ is a partition and the function

$$g(x) = \begin{cases} 0 & x \in [a, c) \\ \frac{1}{2}f(x_0) & x \in [c, d] \\ 0 & x \in (d, b] \end{cases}$$

is piece-wise constant with respect to \mathcal{P} , hence since $f \geq g$ we have

$$\int_{[a,b]} f = \int_{[a,b]} f \geq \text{p.c.} \int_{[a,b]} g = (d-c) \frac{1}{2}f(x_0) > 0$$

which is a contradiction. Hence $f \equiv 0$, proving (ii).

Lemma L17-1 If (X, \int) is an integral pair then for $f, g \in Cts(X, \mathbb{R})$

(i) $f \leq g$ implies $\int f \leq \int g$ " $f \leq g$ means $f(x) \leq g(x)$ for all $x \in X$ "

(ii) $|\int f| \leq \int |f|$

(iii) $\int : Cts(X, \mathbb{R}) \rightarrow \mathbb{R}$ is uniformly continuous.

Proof (i) If $f \leq g$ then $g - f \geq 0$ so $\int g - \int f = \int (g - f) \geq 0$.

(ii) Let $\lambda \in \{1, -1\}$ be such that $\lambda \int f \geq 0$. Then $\lambda f \leq |f|$ so

$$\left| \int f \right| = \lambda \int f = \int \lambda f \leq \int |f|.$$

(iii) Immediate from

$$\left| \int f - \int g \right| = \left| \int (f - g) \right| \leq \int |f - g| \leq \int d_\infty(f, g) = V \cdot d_\infty(f, g)$$

where $V = \int 1$. \square

Exercise L17-3 Give a continuous linear \int not equal to the $\int_{[a,b]}$ of Lemma L17-0 for which $([a,b], \int)$ is also an integral pair.

Recall that by the adjunction property (Theorem L12-4) for X, Y locally compact Hausdorff we have a homeomorphism (Ex. L12-13)

$$\begin{array}{ccc} Cts(X \times Y, Z) & \xrightarrow[\cong]{\Psi_{X,Y,Z}} & Cts(X, Cts(Y, Z)) \\ F & \longmapsto & \{x \mapsto F(x, -)\} \end{array} \quad (4.1)$$

We can use this to define the product of integral pairs. However, in order to prove that the definition is independent of the order of X, Y we will have to use Ex. L16-11 which in turn depends on Urysohn's lemma (which we have not proven). I will provide a proof of this lemma at the end of the semester, but for the moment I will just continue to flag explicitly which results depend on it. In any case, the independence is also a consequence of Fubini's theorem when X, Y are of the form given in Lemma L17-0.

Defⁿ A topological \mathbb{R} -vector space is a vector space V together with a topology on the underlying set of V , such that the structural maps

$$\begin{array}{ll} V \times V \longrightarrow V, & \mathbb{R} \times V \longrightarrow V \\ (v, w) \longmapsto v + w & (\lambda, v) \longmapsto \lambda v \end{array}$$

are all continuous. A topological vector space is in particular a topological group.

Exercise L17-4 Prove that if X is locally compact Hausdorff and V is a topological vector space that $C_b(X, V)$ with the compact-open topology and the pointwise operations (as on p. 6, 7 of Lecture 6) is a topological \mathbb{R} -vector space. (Hint: just copy the proof of Lemma L16-6).

Lemma L17-1 Let $(X, \mathcal{I}_X), (Y, \mathcal{I}_Y)$ be integral pairs. Then $(X \times Y, \mathcal{I}_{X \times Y})$ is an integral pair, called the product integral pair where $\mathcal{I}_{X \times Y}$ is defined so as to make the diagram below commute:

$$\begin{array}{ccc} C_b(X \times Y, \mathbb{R}) & \overset{\mathcal{I}_{X \times Y}}{\dashrightarrow} & \mathbb{R} \\ \Psi_{X, Y, \mathbb{R}} \downarrow \cong & & \uparrow \mathcal{I}_X \\ C_b(X, C_b(Y, \mathbb{R})) & \xrightarrow{\mathcal{I}_Y \circ -} & C_b(X, \mathbb{R}) \end{array} \quad (5.1)$$

Assuming the Urysohn lemma the following diagram also commutes:

$\exists \gamma: Y \times X \rightarrow X \times Y$
is the swap map
 $(y, x) \mapsto (x, y)$

$$\begin{array}{ccc} C_b(X \times Y, \mathbb{R}) & \xrightarrow{\mathcal{I}_{X \times Y}} & \mathbb{R} \\ (-) \circ \gamma & & \uparrow \mathcal{I}_Y \\ C_b(Y \times X, \mathbb{R}) & & \\ \Psi_{Y, X, \mathbb{R}} \downarrow \cong & & \\ C_b(Y, C_b(X, \mathbb{R})) & \xrightarrow{\mathcal{I}_X \circ -} & C_b(Y, \mathbb{R}) \end{array} \quad (5.2)$$

Proof The space $X \times Y$ is compact Hausdorff by Lemma L10-2, Lemma L11-3.

Let us first unpack the definition of $\int_{X \times Y}$. Given $F: X \times Y \rightarrow \mathbb{R}$

$$\begin{array}{ccc}
 C_b(X \times Y, \mathbb{R}) & F & \text{informally} \\
 \Psi \downarrow & & \\
 C_b(X, C_b(Y, \mathbb{R})) & \Psi(F) & x \mapsto F(x, -) \\
 \int_Y \circ (-) \downarrow & & \\
 C_b(X, \mathbb{R}) & \int_Y \circ \Psi(F) & x \mapsto \int_Y F(x, y) dy \\
 \int_X \downarrow & & \\
 \mathbb{R} & \int_X (\int_Y \circ \Psi(F)) & \int_X \int_Y F(x, y) dy dx
 \end{array}$$

As a composite of continuous maps (using Lemma L2-1 for $\int_Y \circ (-)$) it is clear $\int_{X \times Y}$ is continuous. By Exercise L17-4 all spaces involved are topological vector spaces. The map $\Psi_{X, Y, \mathbb{R}}$ is linear since

$$\begin{aligned}
 \Psi_{X, Y, \mathbb{R}}(F + G)(x)(y) &= (F + G)(x, y) \\
 &= F(x, y) + G(x, y) \\
 &= \Psi_{X, Y, \mathbb{R}}(F)(x)(y) + \Psi_{X, Y, \mathbb{R}}(G)(x)(y) \\
 &= [\Psi_{X, Y, \mathbb{R}}(F)(x) + \Psi_{X, Y, \mathbb{R}}(G)(x)](y) \\
 &= [\{\Psi_{X, Y, \mathbb{R}}(F) + \Psi_{X, Y, \mathbb{R}}(G)\}(x)](y)
 \end{aligned}$$

which proves $\Psi_{X, Y, \mathbb{R}}(F + G) = \Psi_{X, Y, \mathbb{R}}(F) + \Psi_{X, Y, \mathbb{R}}(G)$. Similarly one checks that $\Psi_{X, Y, \mathbb{R}}(\lambda F) = \lambda \Psi_{X, Y, \mathbb{R}}(F)$. The map $\int_Y \circ (-)$ is also linear, since $[\int_Y \circ (f + g)](x) = \int_Y (f(x) + g(x)) = \int_Y (f(x)) + \int_Y (g(x))$ and similarly $\int_Y \circ (\lambda f) = \lambda \int_Y \circ f$. So as a composite of linear maps, $\int_{X \times Y}$ is linear.

It remains to check the axioms for an integral pair:

(i) If $F \geq 0$ then for $x \in X$ the function $F(x, -): Y \rightarrow \mathbb{R}$ is non-negative, so since \int_Y is an integral pair $\int_Y F(x, -) \geq 0$. Hence $x \mapsto \int_Y F(x, -)$ is a non-negative function, which has non-negative integral $\int_{X \times Y} F$.

(ii) Suppose $F \geq 0$ and $\int_{X \times Y} F = 0$. That means that the function $F_Y: X \rightarrow \mathbb{R}$ defined by $F_Y(x) = \int_Y F(x, -)$ has $\int_X F_Y = 0$. By the axioms for \int_X we deduce $F_Y \equiv 0$. But then for $x \in X$ $\int_Y F(x, -) = 0$ yields $F(x, -) \equiv 0$ and hence $F \equiv 0$.

Assuming Urysohn, we have to show the two ways around (5.2) are equal as continuous linear maps

$$Cts(X \times Y, \mathbb{R}) \longrightarrow \mathbb{R}$$

But by Lemma L17-2 below it suffices to show they agree on a dense subset A of $Cts(X \times Y, \mathbb{R})$. But as a consequence of Stone-Weierstrass (Ex. L16-11) we know a convenient dense subset, namely the set of all finite sums of products of functions $f: X \rightarrow \mathbb{R}$ and $g: Y \rightarrow \mathbb{R}$, i.e.

$$A = \left\{ \sum_i f_i g_i \mid f_i \in Cts(X, \mathbb{R}), g_i \in Cts(Y, \mathbb{R}) \right\}.$$

Since the two ways around (5.2) are linear, to show they agree on A it suffices to show they agree on a single fg with $f: X \rightarrow \mathbb{R}, g: Y \rightarrow \mathbb{R}$. But then both ways around are easily checked to send $F = fg$ to the product $(\int_X f) \cdot (\int_Y g)$ so we are done. \square

Lemma L17-2 If $f, g : X \rightarrow Y$ are continuous maps of topological spaces, with Y Hausdorff, and $A \subseteq X$ is dense then $f|_A = g|_A$ implies $f = g$.

Proof Consider the continuous map $(\Delta(x) = (x, x))$

$$X \xrightarrow{\Delta} X \times X \xrightarrow{f \times g} Y \times Y$$

since Y is Hausdorff the diagonal $\Delta = \{(y, y) \mid y \in Y\} \subseteq Y \times Y$ is closed, and its preimage under the above map $\{x \in X \mid f(x) = g(x)\}$ is therefore closed in X . Hence if $A \subseteq X$ is dense and $f|_A = g|_A$ then $A \subseteq \{x \mid f(x) = g(x)\}$ and therefore $\{x \mid f(x) = g(x)\} = X$. \square

The outcome of Lemma L17-1 is essentially Fubini's theorem: we may interchange the order of integrals, so roughly speaking (roughly because "dx", "dy" have not entered our notation)

$$\int_X \int_X F(x, y) dx dy = \int_{X \times Y} F(x, y) = \int_X \int_Y F(x, y) dy dx$$

Example L17-1 Combining Lemma L17-0, L17-1 we have an integral pair

$$\left([a_1, b_1] \times \dots \times [a_n, b_n], \int_{[a_1, b_1]} \int_{[a_2, b_2]} \dots \int_{[a_n, b_n]} \right)$$

for any collection of intervals.

We learned in Lecture 7 a few other ways of constructing spaces: disjoint unions and quotients (and pushouts, which were a combination of the two).

It is natural to extend these operations to integral pairs.

Exercise L17-5 (i) Prove that if V, V' are topological \mathbb{R} -vector spaces so is $V \times V'$ with the product topology and the usual operations.

(ii) Let X, Y be locally compact Hausdorff and V a topological \mathbb{R} -vector space. Prove that the bijection

$$\begin{aligned} C_b(X \sqcup Y, V) &\xrightarrow{\cong} C_b(X, V) \times C_b(Y, V) \\ F &\longmapsto (F|_X, F|_Y) \end{aligned}$$

of Ex L7-6 is a linear homeomorphism (that is, an isomorphism of topological vector spaces). Here you are using Ex. L17-4, and (i). (see also Ex. L11-5 and Lemma L10-5). (Hint: you might like to first prove $(X \sqcup Y) \times Z \cong (X \times Z) \sqcup (Y \times Z)$.)

Lemma L17-3 Let $(X, \int_X), (Y, \int_Y)$ be integral pairs. Then $(X \sqcup Y, \int_{X \sqcup Y})$ is an integral pair where $\int_{X \sqcup Y}$ is defined so as to make the diagram below commute:

$$\begin{array}{ccc} C_b(X \sqcup Y, \mathbb{R}) & \xrightarrow{\int_{X \sqcup Y}} & \mathbb{R} \\ \text{Ex. 17-5} \downarrow \cong & & \uparrow + \\ C_b(X, \mathbb{R}) \times C_b(Y, \mathbb{R}) & \xrightarrow{\int_X \times \int_Y} & \mathbb{R} \times \mathbb{R} \end{array}$$

Proof The space $X \sqcup Y$ is compact Hausdorff by Lemma L10-5, Lemma L11-5. The map is continuous and linear as a composite of continuous linear maps (using Ex. L17-5). The axioms of an integral pair are immediate since if $F: X \sqcup Y \rightarrow \mathbb{R}$ then $F \geq 0$ iff. $F|_X \geq 0$ and $F|_Y \geq 0$. \square

Lemma L17-4 Let (X, \int_X) be an integral pair and \sim an equivalence relation on X such that X/\sim is Hausdorff. Then $(X/\sim, \int_{X/\sim})$ is an integral pair where $\int_{X/\sim}$ is the composite (ρ is the quotient map)

$$Cts(X/\sim, \mathbb{R}) \xrightarrow{(-) \circ \rho} Cts(X, \mathbb{R}) \xrightarrow{\int_X} \mathbb{R}$$

Proof The composite is continuous and linear (and X is compact by Lemma L10-1). If $f \geq 0$ then $f \circ \rho \geq 0$ and hence $\int_{X/\sim} f = \int_X (f \circ \rho) \geq 0$. If $f \geq 0$ and $0 = \int_{X/\sim} f = \int_X (f \circ \rho)$ then $f \circ \rho = 0$ and hence $f = 0$. \square

Example L17-2 We define $(S^1, \int_{S^1}) := ([0, 2\pi]/\sim, \int_{[0, 2\pi]})$, where $0 \sim 2\pi$.

Note that as Exercise L17-3 shows, a space can be equipped with many integrals, and for instance using the definition $[0, 1]/\sim$ would include a different integral on S^1 . We choose $[0, 2\pi]$ so that

$$\int_{S^1} 1 = 2\pi.$$

Of course we are free to use a different model of S^1 , say $\mathbb{R}/2\pi\mathbb{Z}$, but while these spaces are homeomorphic if we want to "move" \int_{S^1} to be defined on $\mathbb{R}/2\pi\mathbb{Z}$ we have to specify which homeomorphism $\phi: S^1 \rightarrow \mathbb{R}/2\pi\mathbb{Z}$ we mean and then we would obtain an integral pair from

$$Cts(\mathbb{R}/2\pi\mathbb{Z}, \mathbb{R}) \xrightarrow{(-) \circ \phi} Cts(S^1, \mathbb{R}) \xrightarrow{\int_{S^1}} \mathbb{R}.$$

Anyway, the point is that while we can switch around between $\mathbb{R}/2\pi\mathbb{Z}$, $[0, 2\pi]/\sim$, $[0, 1]/\sim$, $\{(x, y) \mid x^2 + y^2 = 1\}$ as spaces we must be more careful as integral pairs.

Example L17-3 Let X be a finite CW-complex with presentation $X_0, X_1, \dots, X_{n-1}, X_n = X$. For $j \geq 1$ choose a homeomorphism

$$\psi_j : [-1, 1]^j \longrightarrow D^j \quad (\text{the } j\text{-disk})$$

This is not the usual Riemann integral on the disk!

and we make (D^j, \int_{D^j}) an integral pair using ψ_j and $\int_{[-1, 1]^j}$.
We make $X_0 = \{1, \dots, r\}$ an integral pair with (cf. Ex L12-5)

$$Cts(X_0, \mathbb{R}) \longrightarrow \mathbb{R}, \quad f \mapsto \sum_{i=1}^r f(i)$$

Then by induction and Lemmas L17-3, L17-4 we obtain a continuous linear map \int_X s.t. (X, \int_X) is an integral pair. This will depend on the choice of presentation and of the ψ_j , but we can at least choose $\psi_j = \text{id}$ canonically.

Exercise L17-6 Let G be a finite unoriented graph and $X(G)$ the associated CW-complex (Ex. L7-4). Compute $\int_{X(G)} 1$.

Lemma L17-5 If (X, \int) is an integral pair then $d_i^\int(f, g) = \int |f - g|$ defines a metric on $Cts(X, \mathbb{R})$.

Proof (M1) Since $|f - g| \geq 0$ we have $d_i^\int(f, g) \geq 0$.

(M2) If $d_i^\int(f, g) = 0$ then by axiom (ii) of an integral pair $|f - g| = 0$ and hence $f = g$.

(M3) Clearly d_i^\int is symmetric.

(M4) Since $|f - g| + |g - h| \geq |f - h|$ by the triangle inequality in \mathbb{R} , we have by Lemma L17-1 (i) that $\int |f - g| + \int |g - h| \geq \int |f - h|$ and hence the triangle inequality holds.

Solutions to selected exercises

L17-1 Suppose $a_0 + \sum_{n=1}^N (a_n \cos(n\theta) + b_n \sin(n\theta)) = 0$ as functions.

Then differentiating yields

$$\sum_{n=1}^N (-n a_n \sin(n\theta) + n b_n \cos(n\theta)) = 0.$$

$$\sum_{n=1}^N (-n^2 a_n \cos(n\theta) - n^2 b_n \sin(n\theta)) = 0$$

⋮

Setting $\theta = 0$ in all these equations yields

$$\sum_{n=1}^N n b_n = 0$$

$$\sum_{n=1}^N n^2 a_n = 0$$

$$\sum_{n=1}^N n^3 b_n = 0$$

⋮

Collating every second equation gives the matrix eq^N

$$\begin{pmatrix} 1 & 2 & \dots & N \\ 1^2 & 2^2 & \dots & N^2 \\ \vdots & \vdots & \ddots & \vdots \\ 1^N & 2^N & \dots & N^N \end{pmatrix} \begin{pmatrix} b_1 \\ \vdots \\ b_N \end{pmatrix} = 0$$

But this is a Vandermonde matrix whose determinant is nonzero, so we conclude $b_i = 0$ for $1 \leq i \leq N$. Similarly $a_i = 0$ for $1 \leq i \leq N$, and then also $a_0 = 0$. \square
